#### SUMMARY AND OPINION

#### PATHOLOGIC DIAGNOSES:

- I. Pulmonary thromboembolism
  - A. Extensive organizing thromboemboli, bilateral pulmonary arterial vasculature
  - B. Pulmonary edema
  - C. Clinical echocardiogram demonstrated reduced ventricular function
- II. Clinical evidence of septic abortion, per medical records
- ✓ A. Status post fetal abortion by dilatation and evacuation
  - 1. Catheter placement, uterus
  - 2. Complete products of conception and intact placenta with trivascular umbilical cord
  - B. Antemortem blood culture positive for Aerococcus species (per medical records)
  - C. Postmortem uterine swabs/tissue cultures grew rare to few colony growth of Aerococcus species
  - D. Uterine endometritis
    - 1. Microscopic neutrophilic exudates, uterine endometrium and maternal surface of placenta
  - III. Pleural effusions
    - 1. Left chest cavity, 600 mL serous fluid
    - 2. Right chest cavity, 600 mL serous fluid
  - IV. Clinical evidence of acute coagulopathy, per medical records
  - A. Bloody fluid, 100 mL, peritoneal cavity
  - B. Fibrin microthrombi, glomerular
  - C. Parenchymal hemorrhage, left adrenal gland
- ✓ D. Status post multiple blood product transfusions
- V. Status post extensive resuscitation attempts
- A. Contusions, chest
- B. Rib fractures, anterolateral
- VI. Probe patent foramen ovale
- VII. Contusions, minor, extremities

#### SUMMARY AND OPINION:

This 23 year old woman, Keisha Atkins, died of pulmonary thromboembolism due to pregnancy.

✓ According to reports, Ms. Atkins was at a clinic preparing for the final portion of a termination of pregnancy. She presented to the clinic with complaints of cramping pain as expected and was resting preparing for labor. While at the clinic, she noted that she was feeling short of breath, and her oxygen saturation dropped below her baseline. She was placed on oxygen with some improvement of her symptoms. Due to the concerning symptoms, she transferred to University of New Mexico Hospitals, where she continued to have cramping abdominal pain, elevated heart rate and difficulty maintaining normal blood oxygen levels despite supplemental oxygen therapy.

At the hospital, initial testing revealed fluid buildup in the lungs (pulmonary edema), without evidence of significant blood clots, and evaluation of her heart revealed reduced ventricular (pumping chamber) function. Due to rapid decompensation in her clinical status (requiring the placement of a breathing tube) and the concern for a significant infection, she was taken emergently to the operating room to complete the abortion procedure. During the operation, she sustained a cardiac arrest. Extensive resuscitation efforts were ultimately unsuccessful.

Bacterial cultures taken during her hospital admission ultimately grew Aerococcus species in the blood and mixed organisms (including Aerococcus species) in the placental tissue.

Autopsy examination revealed a well-developed, well-nourished young woman with extensive medical intervention. Internal and microscopic examination revealed large, organizing, bilateral pulmonary thromboemboli (large blood clots in the arteries of the lungs). Additional autopsy findings included pulmonary edema with large pleural effusions (fluid in and around the lungs), and a boggy, intact uterus, consistent with recent pregnancy. The lining of the uterus, as well as

the maternal surface of the placenta showed acute inflammation, consistent with the clinical picture of a septic abortion. The placenta and products of conception were otherwise unremarkable. Incidental findings included a patent foramen ovale (opening between two chambers in the heart). Injuries including bruising on the chest and rib fractures were most consistent with resuscitation attempts. The only other injuries detected were minor scattered bruises on the arms and legs.

Toxicology analysis of the antemortem blood revealed a therapeutic level of oxycodone and its breakdown product, oxymorphone.

Postmortem microbiological cultures of the uterus were positive for rare to few colony growth of Aerococcus species. Postmortem bacterial cultures of the heart blood and lungs grew many types of organisms, most consistent with postmortem bacterial overgrowth and/or contamination.

Pulmonary thromboembolism, or blood clots that occlude the arteries of the lungs, may be rapidly fatal, causing death by blocking normal blood flow to the lungs and preventing the normal oxygenation of tissues.

Clinically, Ms. Atkins's evaluation (by CT angiography) for pulmonary thromboembolism (blood clot in the lungs) was negative at her presentation to the hospital. A review of the literature reveals that falsely negative results for this test are typically rare, but such rates have been reported to be as high as 10.7% in one study (1). Essentially, even though the clinical test for a blood clot was negative, Ms. Atkins did have a significant blood clot in her lungs at the time of autopsy that caused her sudden and unexpected death.

When the arteries in the lungs are significantly occluded (blocked) by thromboemboli (blood clots), symptoms and signs such as shortness of breath, increased heart rate, decreased oxygenation of the blood, and chest pain may occur. Ms. Atkins experienced many of these symptoms, along with a rapid deterioration in her respiratory function, reduced heart function, and fluid buildup in her lungs. These clinical findings are all consistent with the postmortem findings of large blood clots in her lungs.

Most often, a blood clot in the lungs actually originates from another source such as the deep leg veins. Risk factors for the development of blood clots include hypercoagulable states, such as pregnancy, among other factors such as high blood pressure, smoking, obesity, and immobility. Ms. Atkins's pregnancy ultimately placed her at increased probability of developing blood clots, which occur at approximately a 4 fold higher rate in pregnant women when compared to the general population (2-4). Pulmonary embolism is the 6th leading cause of maternal mortality in the United States (2-4).

To further complicate her clinical picture, Ms. Atkins also had a high white blood cell count and other clinical features concerning for sepsis (or widespread inflammation and infection) upon her hospital admission. At autopsy, Ms. Atkins did have some evidence of acute inflammation and a positive postmortem bacterial culture for Aerococcus species. However, her overall condition in the hospital was remarkable for significant respiratory distress that decompensated rapidly. While she likely did have an infection from the abortion process, the blockage of her pulmonary arteries by blood clots would have caused the rapid clinical symptoms leading to death, even without infectious or inflammatory complications. The cause of death, therefore, is best certified as pulmonary thromboembolism due to pregnancy. The manner of death is natural.

### **DECLARATION**

The death of ATKINS, KEISHA was investigated by the Office of the Medical Investigator under the statutory authority of the Office of the Medical Investigator.

I, Lauren E Dvorscak, MD, a board certified anatomic, clinical, and forensic pathologist licensed to practice pathology in the State of New Mexico, do declare that I personally performed or supervised the tasks described within this Death Investigation Summary document. It is only after careful consideration of all data available to me at the time that this report was finalized that I attest to the diagnoses and opinions stated herein.

Numerous photographs were obtained along the course of the examination. I have personally reviewed those photographs and attest that they are representative of findings reported in this document.

This document is divided into 8 sections with a final Procedural Notes section:

- 1. Summary and Opinion
- 2. External Examination
- 3. Medical Intervention
- 4. Postmortem Changes
- 5. Evidence of Injuries
- 6. Internal Examination
- 7. Microscopy
- 8. Ancillary Lab Studies

Should you have questions after review of this material, please feel free to contact me at the Office of the Medical Investigator (Albuquerque, New Mexico) - 505-272-3053.

# ADDITIONAL COMMENTS

Received separately is a placenta and products of conception.

The products of conception includes disrupted, variably identifiable fetal parts.

The placenta consists of an overall, unremarkable, intact disc with <10% maternal surface infarction. There is no evidence of purulence on either the maternal or fetal surface. No evidence of placental abruption is on the maternal surface.

The umbilical cord is trivascular.

#### Microscopic description:

Heart: no significant histopathologic diagnosis

Lungs: Organizing thrombi in large and small vessels bilaterally—histologically composed of layered fibrin admixed with erythrocytes and leukocytes into characteristic "lines of Zahn"; no definitive evidence of fetal squamous cells or mucin (AE1/AE3 stain), acellular proteinaceous debris and fluid within alveoli; abundant alveolar macrophages

Kidney: fibrin thrombi within glomerular vasculature

Adrenal: predominately cortical extravasation of erythrocytes

Liver: no significant histopathologic diagnosis

Uterus: exuberant neutrophilic exudate on endometrial surface; arias-stella reaction

Cervix: dilated vascular spaces within cervical stroma associated with interstitial erythrocytes and neutrophils

Placenta: abundant acute inflammation associated with maternal surface

Products of conception: Fetal parts identified

\*Unless otherwise indicated sections are stained only with hematoxylin and eosin (H&E).

#### **Detailed Findings:**

Analysis and Comments	Result	Units	Rpt. Limit	Specimen Source	Analysis By
Oxycodone - Free	38	ng/mL	5.0	001 - Antemortem Blood	LC-MS/MS
Oxymorphone - Free	1.0	ng/mL	1.0	001 - Antemortem Blood	LC-MS/MS

Other than the above findings, examination of the specimen(s) submitted did not reveal any positive findings of toxicological significance by procedures outlined in the accompanying Analysis Summary.

#### **Reference Comments:**

1. Oxycodone - Free (OxyContin®; Roxicodone®) - Antemortem Blood:

Oxycodone is a DEA Schedule II controlled semi-synthetic narcotic analgesic. It is used to control pain associated with such ailments as bursitis, injuries, simple fractures and neuralgia. The addiction liability of oxycodone is about the same as for morphine. This compound should be administered in the smallest effective dose and as infrequently as possible. The usual adult dose of the hydrochloride salt is 5 mg every 6 hr.

Following the oral administration of oxycodone as both sustained-release (Oxycontin®) and regular formulations, peak plasma concentrations of the compound are generally less than 100 ng/mL; however, the sustained-release preparation may also result in peak concentrations of oxycodone less than 10 ng/mL serum. Oxymorphone is a pharmacologically active metabolite of oxycodone that may be seen in blood in very low concentrations.

In overdose, oxycodone can produce stupor, coma, muscle flaccidity, severe respiratory depression, hypotension and cardiac arrest. In twelve oxycodone-related deaths, blood concentrations averaged 1600 ng/mL (range 240 to 8400 ng/mL). However, sustained-release preparations appear to produce adverse reactions, up to and including death, at concentrations of oxycodone well below 1000 ng/mL, especially in combination with other central nervous system depressants, depending on use pattern and route of administration.

Oxymorphone - Free (Numorphan®; Opana®; Oxycodone Metabolite) - Antemortem Blood:

Oxymorphone is a Schedule II semisynthetic opioid analgesic. It is indicated for use in the relief of moderate to severe pain and as a preanesthetic medication. The compound may be administered by injection or by mouth. Oral preparations are available as immediate-release tablets (5 or 10 mg) and as extended-release tablets (5 to 40 mg). Oxymorphone is also a pharmacologically active metabolite of oxycodone.

The mean oral bioavailability of oxymorphone is approximately 10%. The compound is extensively metabolized by reduction to 6-oxymorphol and conjugation to oxymorphone glucuronide and oxymorphone sulfate. Approximately 50% of an oral dose of oxymorphone is eliminated in the urine over 5 days primarily as conjugated oxymorphone and smaller amounts of free oxymorphone and free and conjugated 6-oxymorphol. The mean elimination half-life of oxymorphone is approximately 7.5 to 9.5 hours.

Thirty minutes following a single 5, 10, or 20 mg immediate-release tablet, mean peak plasma concentrations were 1.1, 1.9 and 4.4 ng/mL, respectively. Twenty mg extended-release tablets given every 12 hours for 3 days resulted in a mean peak plasma concentration of 2.5 ng/mL within 3.5 hours following the last dose. Doubling the dose to 40 mg increased the mean peak plasma concentration to 4.5 ng/mL.

Adverse effects of oxymorphone are typical of the opioid group of compounds. Peripheral blood concentrations in 20 oxymorphone related fatalities ranged from 30 to 120 ng/mL.

### Sample Comments:

001 Physician/Pathologist Name: Rebecca Asch-Kendrick, MD/Lauren E Dvorscak, MD

Chain of custody documentation has been maintained for the analyses performed by NMS Labs.

Unless alternate arrangements are made by you, the remainder of the submitted specimens will be discarded six (6) weeks from the date of this report; and generated data will be discarded five (5) years from the date the analyses were performed.

# **Analysis Summary and Reporting Limits:**

All of the following tests were performed for this case. For each test, the compounds listed were included in the scope. The Reporting Limit listed for each compound represents the lowest concentration of the compound that will be reported as being positive. If the compound is listed as None Detected, it is not present above the Reporting Limit. Please refer to the Positive Findings section of the report for those compounds that were identified as being present.
